

supervisor_queue_algorithm

Synopsis

```
supervisor_queue_algorithm = "binding=library[,binding=library...]"
```

Used to specify queuing algorithm(s) used by the supervisor.

binding is the type (either "Perl" or "Internal") of the algorithm, and *library* is the actual library (path to the custom Perl algorithm file, or "cluster", "priority", or "queue" for internal built-in algorithms. By specifying multiple "*binding=library*" combinations, separated by commas, the algorithms may be "stacked"-- algorithms to the left of the list have higher precedence, but if a certain routine isn't specified in it, then the system will try to find one downstream.

Note that, if this parameter is defined in the qb.conf file, the [supervisor_queue_binding](#) and [supervisor_queue_library](#) legacy parameters are ignored.

Example

```
supervisor_queue_algorithm = "Perl=/path/to/my/cool_custom_algorithm.pl,Internal=cluster"
```

Defaults

Internal=cluster
