

# **`__workerTemplatePath_` Gotchas**

Several important things to take note of are:

- On Windows, you must use UNC and the path separator is a forward slash "/".
- This `worker_template_path` should always contain the location of the local jobtypes (the default `worker_template_path` value).
- Compiled jobtypes such as the `cmdline` and `cmdrange` are installed locally by the Worker and should not be centrally located, which necessitates the default template path being included in the new value. This ensures that any updates in future releases of the worker are present in the worker's available jobtypes.
